

why C++?

easier to talk about data representation

"closer to the hardware"

directly allocate memory

more obvious translation to assembly/machine code

heavily related to Java

C++ history

- K&R C (first published 1972) Dennis Ritchie, Bell Labs based on BCPL (1967) meant to be easy to make efficient compilers for
- C with classes (1979) Bjarne Stoustrup, Bell Labs efficiecy of C with features of other languages?
- early C++ (1985) Bjarne Stroustrup, Bell Labs
- ANSI/ISO standard C++ (1998) standardization effort started in 1989 (!) what current compilers try to implement still actively being updated

why not C++?

some not great syntax choices
made in 1980s, standardized in 1990s–2010s
based on C (1970s, standardized in 1980s)
makes compromises for compatibility

incompleteness

the C++ language has a lot of features

...and is still changing

we will teach a particular subset of it

C++ hello world

```
#include <iostream>
using namespace std;
int main() {
    cout << "Hello_World!" << endl;
    return 0;
}</pre>
```

C++ hello world

```
#include <iostream>
using namespace std;
int main() {
    cout << "Hello_World!" << endl;
    return 0;
}</pre>
```

outside of any class! called a function

main

```
int main() { ... }
function outside of any class
must have return type of int
this class: always return 0 from main
```

C++ hello world

```
#include <iostream>
using namespace std;
int main() {
    cout << "Hello_World!" << endl;
    return 0;
}</pre>
```

using directive

```
#include <iostream>
using namespace std;
int main() {
    cout << "Hello_World!" << endl;</pre>
    return 0;
#include <iostream>
int main() {
    std::cout << "Hello_World!" << std::endl;</pre>
    return 0;
```

using directive

```
#include <iostream>
using namespace std;
int main() {
    cout << "Hello_World!" << endl;</pre>
    return 0;
#include <iostream>
int main() {
    std::cout << "Hello_World!" << std::endl;</pre>
    return 0;
```

using directive

```
#include <iostream>
using namespace std;
int main() {
    cout << "Hello_World!" << endl;</pre>
    return 0;
#include <iostream>
int main() {
    std::cout << "Hello_World!" << std::endl;</pre>
    return 0;
```

using single things

```
#include <iostream>
using namespace std;
int main() {
    cout << "Hello_World!" << endl;</pre>
    return 0;
#include <iostream>
using std::cout;
using std::endl;
int main() {
    cout << "Hello_World!" << endl;</pre>
    return 0;
```

C++ hello world

```
#include <iostream>
using namespace std;
int main() {
    cout << "Hello_World!" << endl;
    return 0;
}</pre>
```

instead of import java...

between Java files

```
Foo.java
public class Foo {
    Bar x = new Bar();
                                    Java compiler
                                    looks for
           Bar.java
                                    Bar.java
public class Bar {
```

declare before use

functions, classes must be declared before they are used

compiler processes each file in order compiler processes files seperately

declare before use

functions, classes must be declared before they are used

compiler processes each file in order compiler processes files seperately

declaration versus definition (1)

```
#include <iostream>
bool even(int number);
bool odd(int number) {
    return !even(number);
bool even(int number) {
    if (number == 0) {
        return true;
    } else {
        return odd(number - 1);
```

declaration versus definition (1)

```
#include <iostream>
bool even(int number);
bool odd(int declaration — "function prototype"
    return !d
bool even(int number) {
    if (number == 0) {
        return true;
    } else {
        return odd(number - 1);
```

declaration versus definition (1)

```
#include <iostream>
bool even(int number);
bool odd(int number) definition (and declaration)
    return !even(numb
bool even(int number) {
    if (number == 0) {
        return true;
    } else {
        return odd(number - 1);
```

declaration versus definition (2)

```
#include <iostream>
using namepace std;
int max(int a, int b);
int main(void) {
    int x=37, y=52;
    cout << max(x, y) << endl;
    return 0;
int max(int a, int b) {
    return (a > b) ? a : b;
```

declaration versus definition (2)

```
#include <iostream>
using namepace std;
int max(int a, int b);
             declaration — "function prototype"
int main(void,
    int x=37, y=52;
    cout << max(x, y) << endl;
    return 0;
int max(int a, int b) {
    return (a > b) ? a : b;
```

declaration versus definition (2)

```
#include <iostream>
using namepace std;
int max(int a, int b);
int main(void) {
    int x=37, y=52; definition (and (re)declaration)
    cout << \max(x, y)
    return 0;
int max(int a, int b) {
    return (a > b) ? a : b;
```

functions and prototypes

functions — methods not associated with class

prototype or definition must appear before function can be used

declare before use

functions, classes must be declared before they are used

compiler processes each file in order compiler processes files seperately

declaration versus definition (3)

```
even.cpp
bool even(int number) {
   return number % 2 == 0;
}
```

C++: header files (1)

bool even(int number)

return number % 2 == 0;

```
main.cpp
#include <iostream>
#include "even.h"
int main() {
  if (even(42)) {
    std::cout << "42_is_even"
              << std::endl;
  return 0;
                                     C++ compiler
                                     reads from
            even.h
                                     even.h
extern bool even(int number);
           even.cpp
```

2

C++: header files (2)

```
main.cpp
#include <iostream>
using namespace std;
int main() {
  cout << "Hello,_World!"
       << endl:
                                   C++ compiler
                                   reads from
 iostream (comes w/ compiler)
                                   iostream
  class ostream {
  };
  extern ostream cout;
```

header files

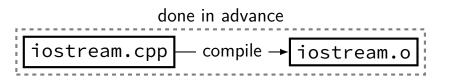

```
header files contain declarations (mostly)
```

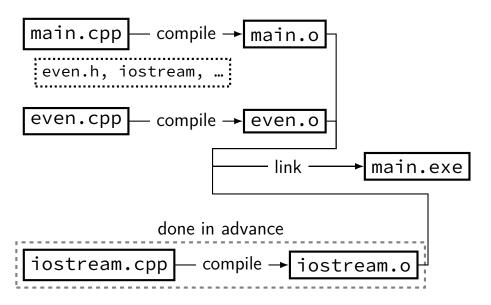

alternative to placing prototypes, etc. in every file convention: every .cpp file has a .h file

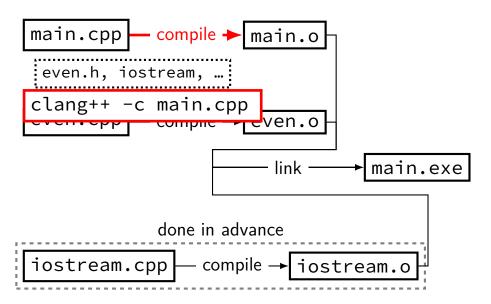

```
main.cpp — compile → main.o

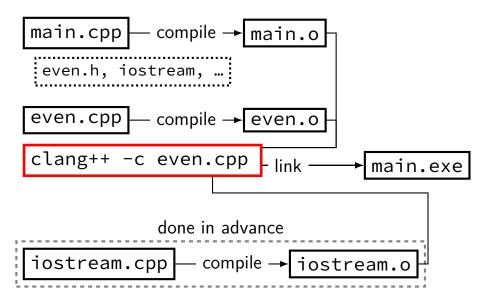

even.h, iostream, ...

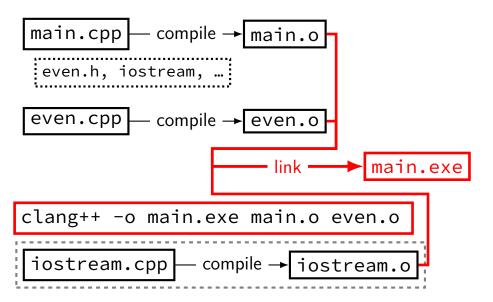

even.cpp — compile → even.o
```

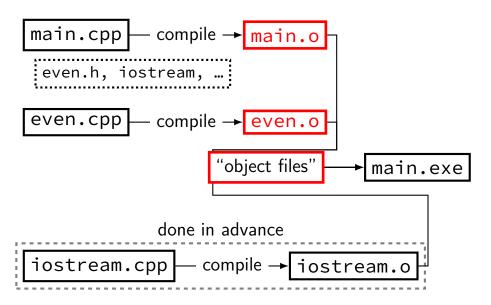

```
main.cpp — compile → main.o
even.h, iostream, ...
even.cpp
           — compile → even.o
  clang++ -o main.exe main.cpp even.cpp
  (does all steps, but doesn't keep some files)
             done in advance
iostream.cpp — compile → iostream.o
```

on commands

```
clang++ file1.cpp file2.cpp
   makes a.out or a.exe
   file1.h, etc. not part of command
clang++ -o main.exe file1.cpp file2.cpp
   makes main.exe
clang++ -Wall -o main.exe file1.cpp file2.cpp
   makes main.exe with more compiler warnings
clang++ -Wall -c file1.cpp
   makes file1.o (not executable)
```

Why clang++?

clang++ our compiler of choice on lab machines better than version of g++ on lab machines/VM

a note on compiler warnings

```
int foo() {
    int bad;
    return 42;
default: almost no warnings
 clang++ -c foo.cpp
add -Wall: more warnings
$ clang++ -Wall -c foo.cpp
foo.cpp:2:9: warning: unused variable 'bad' [-Wunused-variable
    int bad:
1 warning generated.
```

basic I/O

```
#include <iostream>
using std::cout; using std::cin; using std::endl;
// or using namespace std;
int main() {
   int number;
   cout << "Enter_a_number:_";
   cin >> number;
   cout << "You_entered_" << number << endl;
}</pre>
```

basic I/O

```
#include <iostream>
using std::cout; using std::cin; using std::endl;
// or using namespace std;
int main() {
    int number;
    cout << "Enter_a_number:_";</pre>
    cin >> number;
    cout << "You_entered_" << number << endl;</pre>
cin is a global istream object
cout is a global ostream object
```

char

short, int, long

float, double
bool

char

8-bit characters (ASCII, not Unicode) actually integers

short, int, long

float, double bool

```
char
    8-bit characters (ASCII, not Unicode)
    actually integers
short, int, long
    size depends on machine
float, double
bool
```

```
char
    8-bit characters (ASCII, not Unicode)
    actually integers
short, int, long
    size depends on machine
float, double
bool
    yes, not boolean
```

unsigned int, unsigned short, unsigned long like int, short, long — but only positive values (more on this later0

classes

Java: IntCell.java (1)

```
public class IntCell {
    public IntCell() { this(0); }
    public IntCell(int initialValue) {
        storedValue = initialValue;
    }
    public int getValue() {
        return storedValue;
    public void setValue(int newValue) {
        storedValue = newValue;
    }
    private int storedValue;
```

Java: IntCell.java (1)

```
public class IntCell {
    public IntCell() { this(0); }
    public IntCell(int initialValue) {
        storedValue = initialValue;
    }
    public int getValue() {
        return storedValue;
    public void setValue(int newValue) {
        storedValue = newValue;
    }
    private int storedValue;
```

Java: IntCell.java (1)

```
public class IntCell {
    public IntCell() { this(0); }
    public IntCell(int initialValue) {
        storedValue = initialValue;
    }
    public int getValue() {
        return storedValue;
    public void setValue(int newValue) {
        storedValue = newValue;
    }
    private int storedValue;
```

C++ version: three files

IntCell.h — "header file" with declarations only
 #included by both files below

IntCell.cpp — implementation of class

TestIntCell.cpp — example main() that uses class

```
#ifndef INTCELL_H
#define INTCELL_H
class IntCell {
  public:
    IntCell( int initialValue = 0 );
    int getValue() const;
    void setValue(int val);
  private:
    int storedValue;
};
#endif
```

```
#ifndef INTCELL_H
#define INTCELL_H
class IntCell {
  public:
    IntCell( int initialValue = 0 ):
           "boilerplate"
           used to keep preprocessor from including file twice
           (more on this later)
  private:
    int storedValue;
#endif
```

```
#ifndef INTCELL_H
#define INTCELL H
class IntCell {
  public:
    IntCell( int initialValue = 0 ):
                      everything after this is public
    int getValue()
void setValue(i
                      until private:
                       (default is private)
  private:
    int storedValue;
#endif
```

```
#ifndef INTCELL_H
#define INTCELL_H
class IntCell {
  public:
    IntCell( int initialValue = 0 );
    int getValue() cor
void setValue(int constructor declaration
  private:
    int storedValue;
#endif
```

```
#ifndef INTCELL_H
#define INTCELL H
class IntCell {
  public:
    IntCell( int initialValue = 0 );
    int getva default argument
    void set must be part of declaration (not definition)
  private:
    int storedValue;
#endif
```

```
#ifndef INTCELL_H
#define INTCELL H
class IntCell {
 public:
    IntCell( int initialValue = 0 );
    int getValue() const;
    void setValue(int val);
 private:
   int stored could have two explicit constructors, too:
              IntCell();
#endif
              IntCell(int initialValue);
```

```
#ifndef INTCFLL H
#define method declarations
        (official C++ name for methods: "member functions")

    if (denominator == 0) {
        cout << "Denominator_is_zero" << endl;</pre>
    int g = gcd(numerator, denominator);
    num = numerator / g;
    den = denominator / g;
```

```
// default constructor: initialize to 0/1
Rational::Rational() : num(0), den(1) {
Rational::Rational(int numerator, int denominator) {
    if (denom
             probably should throw exception instead?
    int g = gcd(numerator, denominator);
    num = numerator / g;
    den = denominator / g;
```

```
// default constructor: initialize to 0/1
Rational::Rational() : num(0), den(1) {
Rational::Rational(int numerator, int denominator) {
   int g = gcd(numerator, denominator);
   num = numerator
   den = denominator / g;
```

```
// default constructor: initialize to 0/1
Rational::Rational() : num(0), den(1) {
Rational::Ration
    if (denomina member variables initialized in body
        cout << | instead of : LIST syntax
    int g = gcd(numerator, denominator);
    num = numerator
    den = denominator / g;
```

C++: Rational.cpp — times

```
Rational Rational::times(Rational b) const {
    return Rational(num * b.num, den * b.den);
}
```

C++: Rational.cpp — times

```
Rational Rational::times(Rational b) const {
    return Rational(num * b.num, den * b.den);
}
```

syntax to create new Rational object

C++: Rational.cpp — times

```
Rational Rational::times(Rational b) const {
   return Rational(num * b.num, den * b.den);
}
```

need to mark definition const because it's possible to have const and non-const function with same name

IntCell.h

```
#ifndef INTCELL_H

class IntCell {
  public:
    IntCell( int initialValue = 0 ):
           "boilerplate"
           used to keep preprocessor from including file twice
           (more on this later)
  private:
    int storedValue;
#endif
```

preprocessor

two steps to compilation

```
preprocessing
    #include, #define, #ifdef, etc
    can run alone: clang++ -E file.cpp
compilation
```

the preprocessor is dumb

```
Foo.h

class Foo { /* ... */ };

Bar.h

#include "Foo.h"
class Bar { /* ... uses Foo ... */ };

main.cpp

#include "Foo.h"
#include "Bar.h"
```

the preprocessor is dumb

```
Foo.h
class Foo { /* ... */ };
                    Bar.h
#include "Foo.h"
 class Bar { /* ... uses Foo ... */ };
                   main.cpp
#include "Foo.h"
 #include "Bar.h"
In file included from main.cpp:2:
In file included from ./Bar.h:1:
./Foo.h:1:7: error: redefinition of 'Foo'
class Foo {};
./Foo.h:1:7: note: previous definition is here
class Foo {};
```

running the preprocessor alone

```
(some lines omitted)
prompt$ clang++ -E main.cpp
# 1 "main.cpp"
# 1 "./Foo.h" 1
# 2 "main.cpp" 2 (as a temporary file)
# 1 "./Bar.h" 1
# 1 "./Foo.h" 1
class Foo {};
# 2 "./Bar.h" 2
class Bar {};
```

running the preprocessor alone

```
(some lines omitted)
prompt$ clang++ -E main.cpp
# 1 "main.cpp"
# 1 "./Foo.h" 1
                   line numbers/file names for error messages
class Foo {};
# 2 "main.cpp" 2
# 1 "./Bar.h" 1
# 1 "./Foo.h" 1
class Foo {};
# 2 "./Bar.h" 2
class Bar {};
```

#define

```
/* make 'F00' equivalent to 'something' */
#define FOO something
/* make 'BAR' equivalent to '' */
#define BAR
foo is FOO.
bar is BAR.
prompt$ clang++ -E define-example1.cpp
. . .
foo is something.
bar is .
```

#ifndef

#ifndef FOO

```
foo not defined first time
#endif
#define F00
#ifndef F00
if shown after preprocessing:
foo not defined second time
#endif
prompt$ clang++ -E define-example2.cpp
if shown after preprocessing:
foo not defiend first time
```

if shown after preprocessing:

#ifndef

```
#ifndef F00
if shown after preprocessing:
foo not defined first time
#endif
#define F00
#ifndef F00
if shown after preprocessing:
foo not defined second time
#endif
```

omitted since after #define of FOO

```
prompt$ clang++ -E define-example2.cpp
...
if shown after preprocessing:
foo not defiend first time
```

the boilerplate

preprocessor commands (subset)

```
#define NAME replacement
#undef NAMF
#ifndef NAME, #ifdef NAME
#if expression
   e.g. #if defined(X) && defined(Y)
#define NAME(X, Y) thing w/ X and Y
   NAME(foo, bar) \rightarrow thing w/ foo and bar
```

Rational *pointerToFraction;
pointerToFraction = &aFraction;
*pointerToFraction =
          (*pointerToFraction).times(*pointerToFraction);
```

memory

dereference operator

```
(declaration: Type *foo means
"foo is a pointer to Type")

cout << *foo; — output value foo points to
*foo = 42; — set value foo points to to 42</pre>
```

expression: *foo is "value pointed to by foo"

dereference v declare

```
int *pointer = &foo;
// same as:
int *pointer;
pointer = &foo;
```

dereference v declare

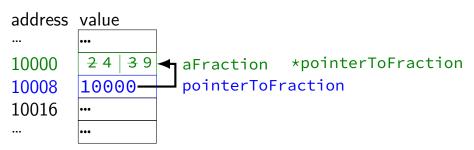

```
int *pointer = &foo;
// same as:
int *pointer;
pointer = &foo;
int *pointer = &foo;
*pointer = bar; // sets foo to bar
```

address-of operator

```
in an expression: &foo is "address of foo"
    (declaration: int &foo = 42; means
    "foo is a reference" — more on that later)
returns address of variable/value
    &variable, &array[42], &obj.instVar
    error if applied to temporary values (e.g. \&(2+2))
cout << &foo; — output address of foo
foo = &bar; — set foo to be a pointer to bar
```

```
Rational aFraction(2, 3);
Rational *pointerToFraction;
pointerToFraction = &aFraction;
*pointerToFraction =
         (*pointerToFraction).times(*pointerToFraction);
```

memory

-> operator

NULL

```
NULL or 0 — explicitly invalid pointer
    for NULL: #include <cstddef>, etc.
int anInt = 42;
int *pointer = NULL;i
int *pointer = 0; // same as above
// NOT same as: int *pointer;
*pointer = anInt; // ERROR: crash (hopefully)
anInt = *pointer; // ERROR: crash (hopefully)
pointer = anInt; // ERROR: type mismatch
if (pointer == NULL) { ... }
if (!pointer) { ... } // same as above
if (pointer != NULL) { ... }
if (pointer) { ... } // same as above
```

crash (hopefully)

but not always — not required

Java — using a null pointer triggers NullPointerException C++ — using a null pointer usually crashes

uninitialized values

uninitialized pointers are not always null
whatever was stored in that part of memory before

might crash or might silently point to something important

```
int valueOne = 42, valueTwo = 100;
int *pointer = &valueOne;
int **ptrToPtr = &pointer;
**ptrToPtr -= 10;

swap

```
void swap(Rational *a, Rational *b) {
    Rational temp = *a;
    b = *a;
    *b = temp;
}
...
Rational first(4, 3);
Rational second(2, 7);
swap(&first, &second);
first.print(); // output: 2/7
```

pointer question

```
int a = 10, b = 20;
int *p; int *q;
p = &a;
q = p;
p = \&b;
*p += 1;
*a = b;
What are the values of a. b?
A. a=10, b=21 D. a=21, b=21
 B. a=11, b=21 E. something else
C. a=20, b=21 F. possible crash
```

C++ local variables (1)

```
Rational getTwoThirds() {
    Rational twoThirds(2, 3);
    return twoThirds;
}
```

two thirds is copied when function returns

C++ local variables (2)

```
HugeValue computeHugeInteger() {
    HugeValue theHugeNumber = ...;
    return theHugeNumber;
}
copy huge number — very inefficiect?
```

C++: pointer to local variables?

```
Rational *brokenGetTwoThirds() {
    Rational twoThirds(2, 3);
    return &twoThirds; // ERROR
}
twoThirds no longer exists when function returns
```

address likely to be reused for something else

new in C++

```
Rational *getTwoThirds() {
    Rational *twoThirdsPointer = new Rational(2, 3);
    return twoThirdsPointer;
HugeValue *computeHugeNumber() {
    HugeValue *theHugeNumber = new HugeValue;
    ... /* set *theHugeNumber */ ...
    return theHugeNumber;
does not copy — returns a pointer
new allocates space somewhere
```

need for delete (1)

```
Rational *getTwoThirds() {
    Rational *twoThirdsPointer;
    twoThirdsPointer = new Rational(2, 3);
    return twoThirdsPointer;
}

void showTwoThirds() {
    Rational *twoThirdsPointer = getTwoThirds();
    twoThirdsPointer->print();
}
```

what happens to where twoThirdsPointer points?

need for delete (1)

"memory leak"

```
Rational *getTwoThirds() {
    Rational *twoThirdsPointer;
    twoThirdsPointer = new Rational(2, 3);
    return twoThirdsPointer;
void showTwoThirds() {
    Rational *twoThirdsPointer = getTwoThirds();
    twoThirdsPointer->print();
what happens to where twoThirdsPointer points?
memory remains used and allocated
```

need for delete (2)

```
Rational *getTwoThirds() {
    Rational *twoThirdsPointer = new Rational(2, 3);
    return twoThirdsPointer;
void showTwoThirds() {
    Rational *twoThirdsPointer = getTwoThirds();
    twoThirdsPointer->print();
int main() { showTwoThirds(); aThing(); return 0; }
      local variable
                           allocated with new
twoThirdsPointer |
                        → twoThirds
```

need for delete (2)

```
Rational *getTwoThirds() {
    Rational *twoThirdsPointer = new Rational(2, 3);
    return twoThirdsPointer;
void showTwoThirds() {
    Rational *twoThirdsPointer = getTwoThirds();
    twoThirdsPointer->print();
int main() { showTwoThirds(); aThing(); return 0; }
      local variable
                          allocated with new
twoThirdsPointer → twoThirds
```

need for delete (2)

```
Rational *getTwoThirds() {
    Rational *twoThirdsPointer = new Rational(2, 3);
    return twoThirdsPointer;
void showTwoThirds() {
    Rational *twoThirdsPointer = getTwoThirds();
    twoThirdsPointer->print();
int main() { showTwoThirds(); aThing(); return 0; }
      local variable
                           allocated with new
twoThirdsPointer |
                       → twoThirds
```

fixed example

```
Rational *getTwoThirds() {
    Rational *twoThirdsPointer = new Rational(2, 3);
    return twoThirdsPointer;
}

void showTwoThirds() {
    Rational *twoThirdsPointer = getTwoThirds();
    twoThirdsPointer->print();
    delete twoThirdsPointer;
    // accessing twoThirdsPointer is now an ERROR
}
```

C++: fixed-sized arrays

```
int arrayOfTenValues[10];
...
int fourthValue = arrayOfTenValues[3];
```

C++: variable sized arrays?

```
int n;
cout << "Enter_size:_";</pre>
cin >> n;
int brokenArrayOfNValues[n];
not part of C++
(but some compilers allow an extension)
$ clang++ -Wall -pedantic -c test.cpp

"memory leak"
```

C++: dynamic arrays (3)

C++: dynamic arrays (3)

new/delete

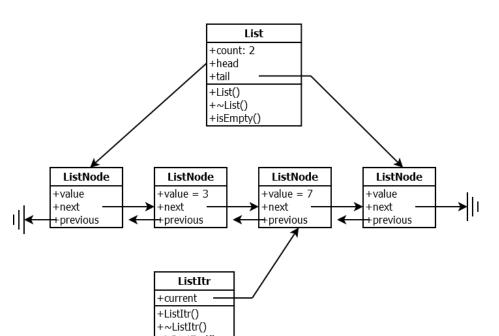

new/delete

delete[] form needed for new with arrays
otherwise, delete won't know the size to free

new/delete

new TYPE(arg1, arg2) — calls constructor built-in constructors that take existing objects

next lab: doubly-linked list

```
class ListNode {
public:
    ListNode();
                                // Constructor
private:
    int value;
    ListNode *next, *previous;
    friend class List;
    friend class ListItr;
};
```

```
class ListNode {
public:
     ListNode();
                                          // Constructor
private:
     int value;
     ListNode *next, *previous;
     friend c * binds to name — declares two pointers;
friend c (why I write * next to names)
};
```

```
class ListNode {
public:
    ListNode();
                                // Constructor
                  the class List can access
private:
                  private members of ListNode
    int value;
    ListNode *next, previous,
    friend class List;
    friend class ListItr;
```

```
class ListNode {
public:
    ListNode();
                                // Constructor
                  the class ListItr can access
private:
                  private members of ListNode
    int value;
    ListNode *next, previous,
    friend class List;
    friend class ListItr;
```

```
class Foo {
public:

    return 0;
```

sizeof operator — how many bytes is X?

```
class Foo { long x, y; };
int main() {
    cout << "sizeof(long):_" << sizeof(long) << endl;</pre>
    cout << "sizeof(Foo):_" << sizeof(Foo) << endl;
    Foo *quux = new Foo;
    Foo *bar = new Foo;
    long diff = ((long)bar)-((long)quux);
    cout << "First_foo:_" << foo << endl;</pre>
    cout << "Second_foo:_" << quux << endl;</pre>
    cout << "Difference:_" << diff << endl;</pre>
    delete quux; delete bar;
    return 0;
```

convert pointers to integers, subtract = distance in memory

```
class Foo { long x, y; };
int main() {
    cout << "sizeof(long):_" << sizeof(long) << endl;</pre>
    cout << "sizeof(Foo):_" << sizeof(Foo) << endl;
    Foo *quux = new Foo;
    Foo *bar = new Foo;
    long diff = ((long)bar)-((long)quux);
    cout << "First_foo:_" << foo << endl;</pre>
    cout << "Second_foo:_" << quux << endl;</pre>
    cout << "Difference:_" << diff << endl;</pre>
    delete quux; delete bar;
    return 0;
```

prints out address

memory.cpp output

```
One (of many) possible output:
sizeof(long): 8
sizeof(Foo): 16
1st Foo: 0x1ec4030
2nd Foo: 0x1ec4050
Difference: 32
32 bytes apart? — 16 extra bytes?
implementation of new storing metadata
    need extra space somewhere to track size, etc.
```

C++ references

```
int x, y;
int &referenceToX = x;
x = 42; y = 100;
cout << referenceToX << "_";  // output: 42
referenceToX = y;  // sets x
cout << referenceToX << "_";  // output: 100
y = 99;
cout << x << "_" << y;  // output: 100 99</pre>
```

references

alternate name for a value

like pointers that are automatically dereferenced

can only bind references at initialization

swap with references

```
void swapWithPointers(int *x, int *y) {
    int temp = *y;
    *y = *x;
    *x = temp;
void swapWithReferences(int &x, int &y) {
    int temp = y;
    y = x;
    x = temp;
```

using swap

```
int main(void) {
    int x = 42, y = 100;
    swapWithPointers(&x, &y);
    cout << x << "_" << y << endl;
        // output: 100 42
    x = 42; y = 100;
    swapWithReferences(x, y);
    cout << x << "_" << y << endl;
        // output: 100 42
    return 0;
```

references to classes

```
class Square {
public:
    int sideLength;
};
Square *ptr = ...;
doSomethingWith(ptr->sideLength);
doSomethingWith((*ptr).sideLength);
Square &ref = ...;
doSomwthingWIth(ref.sideLength);
```

* and &

```
int *p = q — p is a pointer to int
initially contains address q
&y — pointer to y
int *p = &y; cout << *p — outputs y's value
int *p; p = &y; cout << *p — outputs y's value
int &r = y — \frac{r}{bound} is a reference to int bound to y
int &r = y; cout << r — outputs y's value
```

pass-by-value (1)

```
class IntWrapper { public: int value; };
void foo(IntWrapper arg) {
    arg.value = 42;
int main(void) {
    IntWrapper iw;
    iw.value = 100;
    foo(iw);
    cout << iw.value;</pre>
                    A: 42 C: crashes/doesn't compile
what is the output?
                    B: 100 D: none of the above
```

pass-by-value (1)

```
class IntWrapper { public: int value; };
void foo(IntWrapper arg) {
    arg.value = 42;
int main(void) {
    IntWrapper iw;
    iw.value = 100;
    foo(iw);
    cout << iw.value;</pre>
                    A: 42 C: crashes/doesn't compile
what is the output?
                    R: 100 D: none of the above
```

pass-by-value (2)

```
class IntWrapper { public: int value; };
void foo(IntWrapper & arg) {
    arg.value = 42;
int main(void) {
    IntWrapper iw;
    iw.value = 100;
    foo(iw);
                                 arg bound to iw
    cout << iw.value;</pre>
                    A: 42 C: crashes/doesn't compile
what is the output?
```

B: 100 D: none of the above

pass-by-value (2)

```
class IntWrapper { public: int value; };
void foo(IntWrapper & arg) {
    arg.value = 42;
int main(void) {
    IntWrapper iw;
    iw.value = 100;
    foo(iw);
                                 arg bound to iw
    cout << iw.value;</pre>
```

what is the output?

A: 42 C: crashes/doesn't compile
B: 100 D: none of the above

pass-by-value (3)

```
class IntWrapper { public: int value; };
void foo(IntWrapper *arg) {
    arg.value = 42;
int main(void) {
    IntWrapper iw;
    iw.value = 100;
    foo(&iw);
    cout << iw.value;</pre>
                    A: 42 C: crashes/doesn't compile
what is the output?
                    B: 100 D: none of the above
```

pass-by-value (3)

```
class IntWrapper { public: int value; };
void foo(IntWrapper *arg) {
    arg.value = 42;
int main(void) {
    IntWrapper iw;
    iw.value = 100;
    foo(&iw);
    cout << iw.value;</pre>
                    A: 42 C: crashes/doesn't compile
what is the output?
                    B: 100 D: none of the above
```

pass-by-value (3)

```
class IntWrapper { public: int value; };
void foo(IntWrapper *arg) {
    arg.value = 42;
int main(void) {
    IntWrapper iw;
    iw.value = 100;
    foo(&iw);
    cout << iw.value;</pre>
                    A: 42 C: crashes/doesn't compile
what is the output?
                    B: 100 D: none of the above
pointers don't have member variables
```

94

pass-by-value (4)

```
class IntWrapper { public: int value; };
void foo(IntWrapper *arg) {
    arg->value = 42;
int main(void) {
    IntWrapper iw;
    iw.value = 100;
    foo(&iw);
    cout << iw.value;</pre>
                    A: 42 C: crashes/doesn't compile
what is the output?
                    B: 100 D: none of the above
```

pass-by-value (4)

```
class IntWrapper { public: int value; };
void foo(IntWrapper *arg) {
    arg->value = 42;
int main(void) {
    IntWrapper iw;
    iw.value = 100;
    foo(&iw);
    cout << iw.value;</pre>
                    A: 42 C: crashes/doesn't compile
what is the output?
                    B: 100 D: none of the above
```

pass-by-value (4)

```
class IntWrapper { public: int value; };
void foo(IntWrapper *arg) {
    arg->value = 42;
int main(void) {
    IntWrapper iw;
    iw.value = 100;
    foo(&iw);
    cout << iw.value;</pre>
                    A: 42 C: crashes/doesn't compile
what is the output?
                    B: 100 D: none of the above
pointer's value (address) is copied
```

95

avoiding copying

```
bool lessThanCopy(Rational first, Rational second) {
    return first.num * second.den < second.num * first.den;</pre>
bool lessThanNoCopy(const Rational &first, const Rational &sec
    return first.num * second.den < second.num * first.den;</pre>
caller's memory
```

lessThanCopy locals first.num first.num first.den first.den second.num second.num second.den second.den

96

const

```
// no copy, modifies original
void foo(Rational& value) {
    value = Rational(4, 3);
// makes copy, modifies copy
void fooBroken1(Rational value) {
    value = Rational(4, 3); // BROKEN
// makes const(ant) copy, error modifying
void fooBroken1(const Rational value) {
    value = Rational(4, 3); // ERROR
// no copy, error modifying
void fooBroken2(const Rational& value) {
    value = Rational(4, 3); // ERROR
```

return-by-reference

```
int counter; // global variable
int &get_counter_reference() {
    return counter;
}
...
get_counter_reference() = 42;
cout << get counter_reference() << endl; // output: 42</pre>
```

return-by-reference — caution

int &get_counter_reference() {

```
int counter = 0;
    return counter;  // ERROR
}
...
get_counter_reference() = 42;  // ERROR -- writing unallocate
```

```
// FIXME: return-by-pointer?
```

implicit methods

```
class Foo {};
Foo has the following methods:
    Foo() — default constructor
    Foo(const Foo&) — copy constructor
    ~Foo() — destructor
    operator=(const Foo&) — assignment operator
created by compiler, but you can override
```

default constructor/destructor

```
class Foo { public: Foo(); ~Foo(); };
Foo::Foo() { cout << "Foo::Foo()" << endl; }
Foo::~Foo() { cout << "Foo::~Foo()" << endl; }
int main() {
    Foo local:
                                 output:
                                Foo::Foo()
    cout << "(1)\n";
    Foo *ptr = new Foo:
                                (1)
    cout << "(2)\n";
                                Foo::Foo()
    delete ptr;
                                Foo::~Foo()
    cout << "(3)\n";
                                (3)
    return 0;
                                Foo::~Foo()
```

why destructors

```
class DynamicArray {
    ...
    ~DynamicArray();
private:
    int *pointer; // allocated with new int[...]
};
...
DynamicArray::~DynamicArray() {
    delete[] pointer;
}
```

copy constructors, operator= (1)

```
Foo a, b;
// invokes Foo::Foo(const Foo&)
Foo copy1(a);
// invokes Foo::Foo(const Foo&)
Foo copy2 = a;
// invokes Foo::operator=(const Foo&);
b = a;
```

default implementations

```
// equivalent to default implementation:
Rational::Rational(const Rational &other) {
    // copy all member variables
    den = other.den;
    num = other.num;
// equivalent to default implementation:
Rational &Rational::operator=(
        const Rational &other) {
   // copy all members
    den = other.den;
    num = other.num;
    // return reference to this so
    // foo = bar = baz
    // works
    return *this;
```

C++ combined example

test class to demo constructors, operator=, etc.
single file with all examples for test class: cpptest.cpp

this lecture: in independent pieces

```
// test.h:
class test {
    static int idcount;
    const int id;
    int value;
  public:
    test();
    test(int v);
    test(const test& x);
    ~test();
    test& operator=(const test& other);
    friend ostream& operator<<(ostream& out,</pre>
                                    const test& f);
};
```

```
// test.h:
class test {
    static int idcount;
    const int id;
    int value;
  public:
    test();
                          const — must be set in constructor
    test(int v);
    test(const test& x);
    ~test();
    test& operator=(const test& other);
    friend ostream& operator<<(ostream& out,</pre>
                                   const test& f);
};
```

```
// test.h:
class test {
    static int idcount;
    const int id;
    int value;
  public:
                           friend function for
    test();
                           outputting to an ostream (like cout)
    test(int v);
    test(const test& x);
    ~test();
    test& operator=(const test& other);
    friend ostream& operator<<(ostream& out,
                                   const test& f);
};
```

```
// test.cpp:
int test::idcount = 0;

ostream &operator<<(ostream &out, const test &f) {
  out << "test[id=" << f.id << ",v="</pre>
```

/* and similar for constructors */

```
// test.cpp:
int test::idcount = 0;

ostream &operator<<(ostream &out, const test &f) {
  out << "test[id=" << f.id << ",v="</pre>
```

```
// test.cpp:
int test::idcount = 0;
ostream & operator << (ostream & out, const test & f) {
  out << "test[id=" << f.id << ",v="
       << f.value << "]@" << &f:
                               const, so must be on initialization list
  return out;
test::test(const test& x) : id(x.id), value(x.value) {
  cout << "calling_test(" << x <<");_object_created_is_" << *this <</pre>
```

```
// test.cpp:
int test::idcount = 0;
ostream & operator << (ostream & out, const test & f) {
  out << "test[id=" << f.id << ".v="
      << f.value << "]@" << &f;
  return out;
                  called like assignment doesn't actually assign!
test::test(const test& x) : id(x.id), value(x.value) {
  cout << "calling_test(" << x <<");_object_created_is_" << *this <</pre>
```

<< ".operator=(" << other << ")" << endl;

cout << "calling_" << *this

return *this:
